I The specification and Measure of Queueing Systems

The arrival process is generally described in inter arrival times of customers and is denoted $A(t)$

$$A(t) = P[\text{time between arrivals} \leq t]$$

Where each arrival probability is independent of one another. Specifically the interarrival times are independent, identically distributed random variables.

The other statistical quantity of note is the service time.

$$B(x) = P[\text{service time} \leq x]$$

- Storage capacity is often labeled K.
